Network Security Device Authentication Technology

Overview

Device-based authentication links user access to trusted devices instead of passwords. This method uses cryptographic keys stored in secure hardware to verify identity. Instead, Device authentication complements passwords, biometrics, and multi-factor checks to form a layered. IoT device authentication serves as the digital gatekeeper that verifies the identity of every connected device before granting network access. Without robust authentication mechanisms, organizations expose themselves to devastating security breaches, data theft, and operational disruptions that. Establishing trust between a network and an Internet of Things (IoT) device (as defined in NIST Internal Report 8425) prior to providing the device with the credentials it needs to join the network is crucial for mitigating the risk of potential attacks. There are two possibilities for attack.
